## Abstract

## 1 Introduction

## 2 “Theory”

RED-diff is based on the following variational approximation. We wish to sample from  $p(\mathbf{x}_0 | \mathbf{y})$  by fitting a Gaussian variational distribution  $q = \mathcal{N}(\boldsymbol{\mu}, \sigma^2 \mathbf{I})$ . This is essentially solving the MAP estimation problem. We attempt to minimize the KL divergence between  $q$  and  $p$ , which can be written as:

$$D_{\text{KL}}(q(\mathbf{x}_0 | \mathbf{y}) \parallel p(\mathbf{x}_0 | \mathbf{y})) = -\mathbb{E}_{q(\mathbf{x}_0 | \mathbf{y})}[\log p(\mathbf{y} | \mathbf{x}_0)] + D_{\text{KL}}(q(\mathbf{x}_0 | \mathbf{y}) \parallel p(\mathbf{x}_0)) + \log p(\mathbf{y}). \quad (1)$$

The final term  $\log p(\mathbf{y})$  is a constant with respect to the parameters of  $q$  and can thus be ignored. Assuming that the forward model is Gaussian, the first term can be rewritten as:

$$-\mathbb{E}_{q(\mathbf{x}_0 | \mathbf{y})}[\log p(\mathbf{y} | \mathbf{x}_0)] = \frac{-1}{2\sigma_{\text{obs}}^2} \mathbb{E}_{q(\mathbf{x}_0 | \mathbf{y})} [\|\mathcal{A}(\mathbf{x}) - \mathbf{y}\|_2^2]. \quad (2)$$

To deal with the middle term, I think RED-diff uses the following lemmas from [1], although it is not really clear. The first result is:

$$\frac{\partial D_{\text{KL}}(p_t \parallel q_t)}{\partial t} = -\frac{1}{2} \int p_t(\mathbf{x}) g(t)^2 \|\nabla_{\mathbf{x}} \log p_t(\mathbf{x}) - \nabla_{\mathbf{x}} \log q_t(\mathbf{x})\|_2^2 d\mathbf{x}, \quad (3)$$

where  $g(t)$  is the diffusion coefficient (so for EDM  $g(t) = \sigma(t)$ ). According to [1], this implies that

$$D_{\text{KL}}(p_t \parallel q_t) = -\frac{1}{2} \int_0^1 \mathbb{E}_{\mathbf{x} \sim p_t(\mathbf{x})} [g(t)^2 \|\nabla_{\mathbf{x}} \log p_t(\mathbf{x}) - \nabla_{\mathbf{x}} \log q_t(\mathbf{x})\|_2^2] dt. \quad (4)$$

In RED-diff, they use this to claim that:

$$D_{\text{KL}}(q(\mathbf{x}_0 | \mathbf{y}) \parallel p(\mathbf{x}_0)) = \int_0^1 \frac{\beta(t)}{2} \mathbb{E}_{\mathbf{x} \sim p_t(\mathbf{x})} [\|\nabla_{\mathbf{x}} \log q(\mathbf{x}_t | \mathbf{y}) - \nabla_{\mathbf{x}} \log p_t(\mathbf{x})\|_2^2] dt. \quad (5)$$

(We will need to convert between  $\beta$  and  $g$ , since  $\beta$  comes from the VP-SDE.) Conveniently,  $\log q(\mathbf{x}_t | \mathbf{y})$  is available in closed form since  $q$  is Gaussian. RED-diff adds a weighting term in an ad hoc manner. I think we can more rigorously justify this using the theory in [2].

## 3 Results

Table 7: Generalization results on compressed sensing MRI with  $\times 4$  acceleration and raw measurements. Mean and standard deviation are reported over 96 test cases.  $^\dagger$  indicates that we use the result reported in [3].
